

Informatics II

Exercise 6

Mar 29, 2021

Goals:

- Practise pointers of primitive types: int, double, char.
- Practise pointers of arrays.
- Study the linked list data structure and implement it in C.
- Practise linked list with a coding task .

Pointers

Task 1. Pointers, values, and addresses.

- a) Write a short C program that declares and initializes three variables: double `d` , int `i` , and char `ch`. Next declare and initialize a pointer to each of the three variables: pointer `p_d` for `d`, `p_i` for `i`, `p_ch` for `ch`. Print the following information of `d`, `i`, `ch`, `p_d`, `p_i`, and `p_ch`:

- (a) their values
- (b) their addresses
- (c) memory sizes(in bytes)

Use the `"%p"` formatting specifier to print addresses in hexadecimal. You should see addresses that look something like this: `"0xbfe55918"`. The initial characters `"0x"` tell you that hexadecimal notation is being used; the remainder of the digits give the address itself.

Use `"%f"` to print a floating value. Use the `sizeof` operator to determine the memory size allocated for each variable, then use `"%lu"` to print it .

```
1 #include <stdio.h>
2
3 int main()
4 {
5     char ch = 'a';
6     int i = 1;
7     double d = 1.2;
8     char* p_ch = &ch;
9     int* p_i = &i;
10    double* p_d = &d;
11
12    printf("The address of ch is %p\n", &ch);
13    printf("The address of i is %p\n", &i);
14    printf("The address of d is %p\n", &d);
```

```

15 printf("The_address_of_p_ch_is_%p\n", &p_ch);
16 printf("The_address_of_p_i_is_%p\n", &p_i);
17 printf("The_address_of_p_d_is_%p\n", &p_d);
18
19 printf("The_value_of_ch_is_%c\n", ch);
20 printf("The_value_of_i_is_%d\n", i);
21 printf("The_value_of_d_is_%f\n", d);
22 printf("The_value_of_p_ch_is_%p\n", p_ch);
23 printf("The_value_of_p_i_is_%p\n", p_i);
24 printf("The_value_of_p_d_is_%p\n", p_d);
25
26 printf("The_size_of_ch_is_%lu_bytes\n", sizeof(ch));
27 printf("The_size_of_i_is_%lu_bytes\n", sizeof(i));
28 printf("The_size_of_d_is_%lu_bytes\n", sizeof(d));
29 printf("The_size_of_p_ch_is_%lu_bytes\n", sizeof(p_ch));
30 printf("The_size_of_p_i_is_%lu_bytes\n", sizeof(p_i));
31 printf("The_size_of_p_d_is_%lu_bytes\n", sizeof(p_d));
32 }

```

b) Check the two C functions, *swap_nums* seems to work, but *swap_pointers* does not. Fix it.

```

1 #include <stdio.h>
2
3 void swap_nums(int *x, int *y)
4 {
5     int tmp;
6     tmp = *x;
7     *x = *y;
8     *y = tmp;
9 }
10
11 void swap_pointers(char *x, char *y)
12 {
13     char *tmp;
14     tmp = x;
15     x = y;
16     y = tmp;
17 }
18
19 int main()
20 {
21     int a,b;
22     char *s1,*s2;
23     a = 3; b=4;
24     swap_nums(&a,&b);
25     printf("a_is_%d\n", a);
26     printf("b_is_%d\n", b);
27     s1 = "I_should_print_second";
28     s2 = "I_should_print_first";
29     swap_pointers(s1,s2);
30     printf("s1_is_%s\n", s1);
31     printf("s2_is_%s\n", s2);
32     return 0;
33 }

```

```

1 #include <stdio.h>

```

```

2
3 void swap_nums(int *x, int *y)
4 {
5     int tmp;
6     tmp = *x;
7     *x = *y;
8     *y = tmp;
9 }
10
11 void swap_pointers(char **x, char **y)
12 {
13     char *tmp;
14     tmp = *x;
15     *x = *y;
16     *y = tmp;
17 }
18
19 int main()
20 {
21     int a,b;
22     char *s1,*s2;
23     a = 3; b=4;
24     swap_nums(&a,&b);
25     printf("a_is_%d\n", a);
26     printf("b_is_%d\n", b);
27     s1 = "I_should_print_second";
28     s2 = "I_should_print_first";
29     swap_pointers(&s1,&s2);
30     printf("s1_is_%s\n", s1);
31     printf("s2_is_%s\n", s2);
32     return 0;
33 }

```

Task 2. Pointers are widely used to access strings and arrays. In this exercise, we use pointers instead of the `[]` operator to manipulate strings and arrays.

- a) Write a program in C to calculate the length of the string **using pointers**.

```

1 #include <stdio.h>
2 int calculateLength(char*);
3
4 int main()
5 {
6     char str1[100];
7     int l;
8     printf("\n\nPointer.: Calculate the length of the string.\n");
9     printf("-----\n");
10
11     printf("Input a string.:");
12     fgets(str1, sizeof str1, stdin);
13
14     l = calculateLength(str1);
15     printf("The length of the given string_%s is: %d", str1, l-1);
16     printf("\n\n");
17
18 }

```

```

19
20 int calculateLength(char* ch) // ch = base address of array str1 ( &str1[0] )
21 {
22     int ctr = 0;
23     while (*ch != '\0')
24     {
25         ctr++;
26         ch++;
27     }
28     return ctr;
29 }

```

b) Write a program in C to print a string in reverse **using pointers**.

```

1  #include <stdio.h>
2  int main()
3  {
4      char str1[50];
5      char revstr[50];
6      char *stptr = str1;
7      char *rvptr = revstr;
8      int i=-1;
9      printf("\n\nPointer.: Print a string in reverse order.\n");
10     printf("-----\n");
11     printf("Input a string:");
12     scanf("%s",str1);
13     while(*stptr)
14     {
15         stptr++;
16         i++;
17     }
18     while(i≥0)
19     {
20         stptr--;
21         *rvptr = *stptr;
22         rvptr++;
23         --i;
24     }
25     *rvptr='\0';
26     printf("Reverse of the string is: %s\n\n",revstr);
27     return 0;
28 }

```

c) Write a program in C to print the elements of an array in reverse order **using pointers**.

```

1  #include <stdio.h>
2  int main()
3  {
4      int n, i, arr1[15];
5      int *pt;
6      printf("\n\nPointer.: Print the elements of an array in reverse order.\n");
7      printf("-----\n");
8
9      printf("Input the number of elements to store in the array (max 15):");
10     scanf("%d",&n);
11     pt = &arr1[0]; // pt stores the address of base array arr1

```

```

12  printf("Input number of elements in the array:\n",n);
13  for(i=0;i<n;i++) {
14      printf("element-%d:",i+1);
15      scanf("%d",pt);//accept the address of the value
16      pt++;
17  }
18
19  pt = &arr1[n - 1];
20
21  printf("\nThe elements of array in reverse order are:");
22
23  for (i = n; i > 0; i--)
24  {
25      printf("\nelement-%d:%d", i, *pt);
26      pt--;
27  }
28  printf("\n\n");
29 }

```

d) Write a C program to multiply two matrix **using pointers**.

```

1  /**
2   * C program to multiply two matrix using pointers
3   */
4
5  #include <stdio.h>
6
7  #define ROW 3
8  #define COL 3
9
10
11  /* Function declarations */
12  void matrixInput(int mat[][COL]);
13  void matrixPrint(int mat[][COL]);
14  void matrixMultiply(int mat1[][COL], int mat2[][COL], int res[][COL]);
15
16
17
18  int main()
19  {
20      int mat1[ROW][COL];
21      int mat2[ROW][COL];
22      int product[ROW][COL];
23
24
25      /*
26       * Input elements in matrices.
27       */
28      printf("Enter elements in first matrix of size %dx%d\n", ROW, COL);
29      matrixInput(mat1);
30
31      printf("Enter elements in second matrix of size %dx%d\n", ROW, COL);
32      matrixInput(mat2);
33
34
35      // Call function to multiply both matrices

```

```
36     matrixMultiply(mat1, mat2, product);
37
38
39     // Print product of both matrix
40     printf("Product of both matrices is:\n");
41     matrixPrint(product);
42
43     return 0;
44 }
45
46
47
48 /**
49  * Function to input elements in matrix from user.
50  *
51  * @mat Two-dimensional array to store user input.
52  */
53 void matrixInput(int mat[][COL])
54 {
55     int row, col;
56
57     for (row = 0; row < ROW; row++)
58     {
59         for (col = 0; col < COL; col++)
60         {
61             scanf("%d", (*(mat + row) + col));
62         }
63     }
64 }
65
66
67
68
69 /**
70  * Function to print elements in a two-dimensional array.
71  *
72  * @mat Two-dimensional array to print.
73  */
74 void matrixPrint(int mat[][COL])
75 {
76     int row, col;
77
78     for (row = 0; row < ROW; row++)
79     {
80         for (col = 0; col < COL; col++)
81         {
82             printf("%d ", (*(mat + row) + col));
83         }
84
85         printf("\n");
86     }
87 }
88
89
90
91
```

```

92  /**
93   * Function to multiply two matrices.
94   *
95   * @mat1 First matrix
96   * @mat2 Second matrix
97   * @res Resultant matrix to store product of both matrices.
98   */
99  void matrixMultiply(int mat1[][COL], int mat2[][COL], int res[][COL])
100 {
101     int row, col, i;
102     int sum;
103
104     for (row = 0; row < ROW; row++)
105     {
106         for (col = 0; col < COL; col++)
107         {
108             sum = 0;
109
110             /*
111              * Find sum of product of each elements of
112              * rows of first matrix and columns of second
113              * matrix.
114              */
115             for (i = 0; i < COL; i++)
116             {
117                 sum += (*(mat1 + row) + i) * (*(mat2 + i) + col);
118             }
119
120             /*
121              * Store sum of product of row of first matrix
122              * and column of second matrix to resultant matrix.
123              */
124             *(res + row) + col = sum;
125         }
126     }
127 }
128 }
129 }

```

Linked Lists

Task 3. We have seen how a linked list works from the lectures. Now let us implement the linked list data structure in C.

- a) *void createNodeList(int n)* and *void displayList()* that create and display Singly Linked List (of n nodes).

```

1  #include <stdio.h>
2  #include <stdlib.h>
3
4  struct node
5  {
6      int num; //Data of the node
7      struct node *nextptr; //Address of the node
8  }*stnode;

```

```

9
10 void createNodeList(int n); //function to create the list
11 void displayList(); //function to display the list
12 void insertNode(int num, int pos); //function to insert node at the middle
13 void deleteNode(int pos); //function to delete a node from middle
14
15 void createNodeList(int n)
16 {
17     struct node *fnNode, *tmp;
18     int num, i;
19     stnode = (struct node *)malloc(sizeof(struct node));
20     if(stnode == NULL) //check whether the stnode is NULL and if so no memory allocation
21     {
22         printf("Memory can not be allocated.");
23     }
24     else
25     {
26         // reads data for the node through keyboard
27         printf("Input data for node 1:");
28         scanf("%d", &num);
29         stnode->num = num;
30         stnode->nextptr = NULL; //Links the address field to NULL
31         tmp = stnode;
32         //Creates n nodes and adds to linked list
33         for(i=2; i<=n; i++)
34         {
35             fnNode = (struct node *)malloc(sizeof(struct node));
36             if(fnNode == NULL) //check whether the fnNode is NULL and if so no memory allocation
37             {
38                 printf("Memory can not be allocated.");
39                 break;
40             }
41             else
42             {
43                 printf("Input data for node %d:", i);
44                 scanf("%d", &num);
45
46                 fnNode->num = num; // links the num field of fnNode with num
47                 fnNode->nextptr = NULL; // links the address field of fnNode with NULL
48
49                 tmp->nextptr = fnNode; // links previous node i.e. tmp to the fnNode
50                 tmp = tmp->nextptr;
51             }
52         }
53     }
54 }
55
56 void displayList()
57 {
58     struct node *tmp;
59     if(stnode == NULL)
60     {
61         printf("No data found in the empty list.");
62     }
63     else
64     {

```

```

65     tmp = stnode;
66     while(tmp != NULL)
67     {
68         printf("Data=%d\n", tmp->num); // prints the data of current node
69         tmp = tmp->nextptr; // advances the position of current node
70     }
71 }
72 }

```

b) *void insertNode(int num, int pos)* that inserts a new node at the middle of Singly Linked List.

```

1 void insertNode(int num, int pos)
2 {
3     int i;
4     struct node *fnNode, *tmp;
5     fnNode = (struct node*)malloc(sizeof(struct node));
6     if(fnNode == NULL)
7     {
8         printf("Memory can not be allocated.");
9     }
10    else
11    {
12        fnNode->num = num; //Links the data part
13        fnNode->nextptr = NULL;
14        tmp = stnode;
15        for(i=2; i<=pos-1; i++)
16        {
17            tmp = tmp->nextptr;
18
19            if(tmp == NULL)
20                break;
21        }
22        if(tmp != NULL)
23        {
24            fnNode->nextptr = tmp->nextptr; //Links the address part of new node
25            tmp->nextptr = fnNode;
26        }
27        else
28        {
29            printf("Insert is not possible to the given position.\n");
30        }
31    }
32 }

```

c) *void deleteNode(int pos)* that deletes a node from the middle of Singly Linked List.

```

1 void deleteNode(int pos)
2 {
3     int i;
4     struct node *toDelMid, *preNode;
5
6     if(stnode == NULL)
7     {
8         printf("There are no nodes in the List.");
9     }
10    else

```

```

11     {
12         toDelMid = stnode;
13         preNode = stnode;
14
15         for(i=2; i≤pos; i++)
16         {
17             preNode = toDelMid;
18             toDelMid = toDelMid->nextptr;
19
20             if(toDelMid == NULL)
21                 break;
22         }
23         if(toDelMid != NULL)
24         {
25             if(toDelMid == stnode)
26                 stnode = stnode->nextptr;
27
28             preNode->nextptr = toDelMid->nextptr;
29             toDelMid->nextptr = NULL;
30             free(toDelMid);
31         }
32         else
33         {
34             printf(" _Deletion_can_not_be_possible_from_that_position.");
35         }
36     }
37 }

```

d) *int FindElement(int FindElem)* that searches an existing element in a Singly Linked List.

```

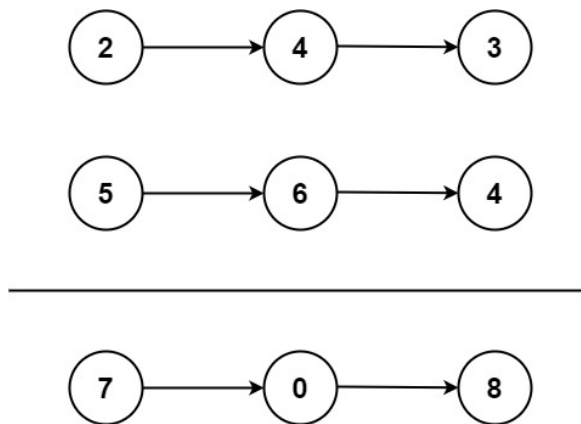

1  int FindElement(int FindElem)
2  {
3      int ctr=1;
4      struct node* ennode = stnode;
5      while(ennode!=NULL)
6      {
7          if(ennode->num==FindElem)
8              return ctr;
9          else
10             ctr++;
11             ennode=ennode->nextptr;
12     }
13     return -1;
14 }

```

Task 4. You are given two non-empty linked lists representing two non-negative integers. The digits are stored in reverse order, and each of their nodes contains a single digit. Add the two numbers and return the sum as a linked list.

You may assume the two numbers do not contain any leading zero, except the number 0 itself.

Example 1:

Input: $l1 = [2, 4, 3]$, $l2 = [5, 6, 4]$
 Output: $[7, 0, 8]$
 Explanation: $342 + 465 = 807$.

Example 2:

Input: $l1 = [0]$, $l2 = [0]$
 Output: $[0]$

Example 3:

Input: $l1 = [9, 9, 9, 9, 9, 9, 9]$, $l2 = [9, 9, 9, 9]$
 Output: $[8, 9, 9, 9, 9, 0, 0, 0, 1]$

Since the two input linked lists store digits in a reverse order, we can add up the same position of the two linked lists directly.

We iterate the two input linked lists at the same time, sum up the digits position by position, and also add the carried value from the previous position.

If the two input linked lists have different lengths, we can think of the short one have some 0s in the end.

In addition, when we finish the iteration if we still have a carried value $carry > 0$, we need to append a new node in the end that have value $carry$.

```

1 struct node* addTwoNumbers(struct node* l1, struct node* l2) {
2     struct node *head = NULL, *tail = NULL;
3     int carry = 0;
4     while (l1 || l2) {
5         int n1 = l1 ? l1->num : 0;
6         int n2 = l2 ? l2->num : 0;
